### **I. POPULATION DENSITIES AROUND URANIUM MINES**

1. Previously in the UNSCEAR 2000 Report [U1] and earlier, the Committee assumed a population density of  $3 \text{ km}^{-2}$  from 0 to 100 km around a uranium mine/mill tailings site and then a density of  $25 \text{ km}^{-2}$  from 100 to 2,000 km. Since this time the location of the mines producing most of the world's uranium has changed and therefore further information on population densities was obtained.

2. Table 1 below is derived from information on uranium mines provided by the World Nuclear Association website [W1]. The site states: "Uranium mines operate in some 20 countries, though in 2014 some 54% of the world's production came from just ten mines in six countries, these six countries providing 85% of the world's mined uranium".

3. Information is available on the population distribution and densities around operating mines in Australia and Canada and the densities are summarized in table 2. The other major uranium mining areas are Kazakhstan, Niger, Namibia and the Zabaykalsky Krai region of Russia near the Sino-Russian border. According to the World Bank, the population densities for these geographical regions in 2015 were: Kazakhstan:  $6.0 \text{ km}^{-2}$ ; Niger:  $16 \text{ km}^{-2}$ ; Namibia:  $3 \text{ km}^{-2}$  [W3]. The World Atlas indicates that the corresponding value for Zabaykalsky Krai is:  $2.7 \text{ km}^{-2}$  [W2].

4. However, the locations of the major mines are all at some distance from the main population centres in these countries and so the population densities around the mines are expected to be lower than the value for the country or region as a whole.

5. From these data the Committee agreed that a population density of  $5 \text{ km}^{-2}$  should be used for all distances for uranium mines and mill tailings sites.

**Table 1. The largest-producing uranium mines in 2014 [W1]**

<i>Mine</i>	<i>Country</i>	<i>Main owner</i>	<i>Type</i>	<i>Production (tU)</i>	<i>% of world production</i>
McArthur River	Canada	Cameco	underground	7 356	13

**Table 2. Population densities for uranium mines in Australia and Canada**

<i>Site</i>	<i>Population density (km<sup>-2</sup>)</i>	
	<i>0–100 km</i>	<i>100–2 000 km</i>
Key Lake, Canada <sup>a</sup>	0	4.6
McClean Lake, Canada <sup>a</sup>	0.07	
Ranger, Australia <sup>b</sup>	0.1	0–0.2
Olympic Dam, Australia <sup>b</sup>	0.2	0.3–3.1
Beverley, Australia <sup>b</sup>	0	0.3–3.2
Honeymoon, Australia <sup>b</sup>	0.6	2.1–3.7
Former mines, Australia <sup>b</sup>	0.1–3.9	0–4.1

<sup>a</sup> The population estimates for Canadian mines were calculated in ArcGIS using ESRI's World Population Estimate population density map [E1]. Additional details for the population data can be found here: <http://www.arcgis.com/home/item.html?id=ac0401d78fa24a10a915ffe50f35afe>.

Population data were obtained by 100 km radial intervals (i.e. 0–100 km, 100–200 km, 1 900–2 000 km) and the totals summed. Because all the operating Canadian uranium mine/mill sites are relatively close together, (approx. 160 km between two furthest sites Key Lake and McClean Lake), and are located in remote regions, the radial intervals were centred around Key Lake Mill, the southernmost uranium mine/mill, which was presumed to result in the most conservative estimate of population because it is closer to the more populous USA. The coordinate system used was a WGS UTM Zone 13N Projection to minimize error in population estimates associated with mapping the earth on a two-dimensional plane.

<sup>b</sup> Australian Bureau of Statistics, 2011 Census of Population and Housing [A1].

## II. DERIVATION OF POPULATION DENSITIES AROUND NUCLEAR POWER SITES

### A. Introduction

6. UNEP/DEWA/GRID-Geneva developed three geoprocessing models able to generate several thousand geodesic buffers of various types and sizes needed to derive population numbers around nuclear power sites within specified buffer zones.

7. Population data were extracted both for sites with any kind of reactor status and for sites with operating reactors only. Tabular results were derived from the population data in three different ways: by nuclear power site, by UNEP GEO region and also for Europe allowing for the effect of double counting.<sup>1</sup>

### B. Materials and methods

8. In order to deliver the expected outputs, three large geoprocessing models were developed using ESRI ModelBuilder in ArcGIS 10. ModelBuilder can be thought of as a visual programming language for building workflows. A number of advanced techniques were implemented, such as in-line variable substitution, iteration, preconditions and if-then-else logic.

9. Based on user input data and input values, the geoprocessing models automatically generated geodesic buffers, manipulated them in various ways and extracted population from a global population distribution data set. Population data were provided by nuclear power site, by UNEP GEO region and also for Europe with the effect of double counting.

10. The following buffer types and areas were generated around each nuclear power site:

(a) For the output provided by nuclear power site (table 3 and table 4) – one disk buffer with a radius of 10 km and five ring buffers with radius 10 km to 100 km, 100 km to 500 km, 500 km to 1,000 km, 1,000 km to 1,500 km and 1,500 km to 2,000 km;

(b) For the output provided by UNEP GEO region and subregion (table 5 and table 6) – one disk buffer with a radius of 100 km and one ring buffer with radius 100 km to 1,500 km;

(c) For the output provided for Europe with the effect of double counting (table 7 and table 8) – one disk buffer with a radius of 100 km.

11. The required population outputs were produced using the three models mentioned earlier. Each model generated and combined polygons in various ways, iterated over polygons to produce new shapefiles, extracted by mask the cells of a raster population grid, calculated fields and combined multiple tabular files. For each polygon and sometimes group of polygons, the following features were created: a shapefile, a grid and a DBF file. The key applications of the models were as follows:

(a) Using the first model, population by site was determined for each nuclear power site, for a given buffer radius and type, the population located within the buffer area. It contained eight submodels;

---

<sup>1</sup> Population located within overlapping buffers is counted more than once.

(b) In the second model, population by region was determined for each country, for aggregated buffers of a given radius and type around the nuclear power sites, together with the total population located within the aggregated buffer area (population within overlapping buffers is counted once). It contained seven submodels;

(c) Using the third model, population by region with the effect of double counting, was determined for each country, for each buffer part of a given radius and type around the nuclear power sites, the total population located within the areas of the buffer parts (population within overlapping buffers is counted more than once). It contained eight submodels.

12. The following data sets were used by the models:

- (a) UNEP/DEWA/GRID-Geneva Nuclear Power Stations of the World (status 2010);
- (b) LandScan (2008) High Resolution Global Population Data Set, UT-Battelle, LLC, ORNL, DoD;
- (c) International Boundary Resources, UN Cartographic Section (with expanded coastlines).

### **1. Effect of overlapping buffers on population (double counting)**

13. Table 3 and table 4 (obtained by the first model) show population by nuclear power site for six specified buffer radii (one disk buffer and five ring buffers). For a given site (one site per row), population numbers can be added, because the buffers are non-overlapping (0–10 km, 10–100 km, 100–500 km, ...). For a given buffer radius (one buffer radius per column), population numbers cannot be added, because many buffers are partly overlapping with each other and population within these intersections would be double-counted. These two tables should only be used to obtain, for a given site, the population located around the site within buffers of various sizes.

14. Table 5 and table 6 (obtained by the second model) show population by UNEP GEO region and subregion for two buffer radii (one disk buffer and one ring buffer). For a given region or subregion, population numbers can be added, because the buffers are non-overlapping (0–100 km, 100–1,500 km). For a given buffer radius, population numbers can also be added, because the buffers are aggregated and intersected with the countries. Population located within a buffer intersection (before the aggregation process) is counted once, and thus, there is no effect of overlapping buffers.

15. Table 7 and table 8 (obtained by the third model) show population by the UNEP GEO European region and subregion for one buffer radius (one disk buffer) with the effect of overlapping buffers (double counting). On purpose, the population within a buffer intersection was counted more than once to take into account the exposure from several nuclear power sites. Therefore, the obtained population numbers are much higher than the actual population located within the buffers.

**Table 3. Population (2008) by nuclear power site with any kind of reactor status (274 sites)**
